Equations of Change: Linear and Exponential Functions

Definition: An equation of the form $\frac{df}{dx} = \text{Right-hand side}$ is called an equation of change, also known as **differential equation**.

Equations of Change and Linear Functions

The equation of change $\frac{df}{dx} = m$, where m is a **constant**, says that f has a constant rate of change m and hence that f is a **linear function with slope m** . That is, $f = mx + b$.

An initial condition is needed to determine the value of b .

Equations of Change and Exponential Functions

The equation of change $\frac{df}{dx} = rf$, where r is a constant, says that f has a constant proportional (and hence percentage) rate of change and is therefore an **exponential function**. The **exponential growth rate for f is r** , so the growth (or decay) factor is e^r . That is,

$$f = Pe^{rx}$$

Or

$$f = P \times (e^r)^x$$

where P is the initial value of f .

Example 1: On Mars, a falling object satisfies the equation of change $\frac{dV}{dt} = 12.16$, where V is downward velocity in feet per second and t is time in seconds.

- What is the value of **acceleration** due to gravity on Mars?
- Suppose an astronaut stands atop a cliff on Mars and throws a rock downward with an initial velocity of 8 feet per second. What is the velocity of the rock 3 seconds after release?

(a) $a = \frac{dV}{dt} = 12.16$ $\frac{\text{ft per second}}{\text{second}}$
 ft per sec^2

(b) $V(t) = 12.16t + b$ ← initial value
 $V(t) = 12.16t + 8$

$$V(3) = 12.16(3) + 8 = 44.48 \text{ ft/sec}$$

Example 2: You open an account by investing \$250 with a financial institution that advertises an APR of 5.75%, with continuous compounding.

- Find an exponential formula for the balance in your account as a function of time. In your answer, give both the standard form and the exponential function.
- What account balance would you expect 5 years after your initial investment? Answer this question using both of the forms you found in part a). Which do you think gives more accurate answer? Why?

(a) $r = .0575$ $P = 250$

$$B(t) = 250 e^{.0575t}$$

(b)

$$B(5) = 250 e^{.0575(5)}$$

$$= \$333.27$$

$$B(t) = 250 \times 1.0592^t$$

$$B(5) = 250 \times (1.0592)^5$$

Example 3: What is the common mathematical term for an equation of change?

$\$ 333.30$

diff. eq.

Example 4: If f satisfies the equation of change $\frac{df}{dx} = m$, what kind of function is f ?

linear

Example 5: If f satisfies the equation of change $\frac{df}{dx} = 3$, then f is a linear function. What is the slope of f ?

3

Example 6: If f satisfies the equation of change $\frac{df}{dx} = cf$, what kind of function is f ?

expon.

Example 7: If f satisfies the equation of change $\frac{df}{dx} = 5f$, then f is an exponential function and hence can be written as $f = Ae^{ct}$. What is the value of c ?

$c = 5$

Example 8: Solve the equation of change $\frac{df}{dx} = 5$ if the initial value of f is 3.

$$f(x) = 5x + 3$$

Example 8: Solve the equation of change $\frac{df}{dx} = 5f$ if the initial value of f is 2. Use the alternative form for exponential function.

$$f(x) = 2e^{5x}$$
