# Row Space

## Row Space

The set of all linear combinations of the row vectors of a matrix  $A$  is called the **row space** of  $A$  and is denoted by  $\text{Row } A$ .

## Example

Let

$$A = \begin{bmatrix} -1 & 2 & 3 & 6 \\ 2 & -5 & -6 & -12 \\ 1 & -3 & -3 & -6 \end{bmatrix} \quad \text{and} \quad \begin{aligned} \mathbf{r}_1 &= (-1, 2, 3, 6) \\ \mathbf{r}_2 &= (2, -5, -6, -12) \\ \mathbf{r}_3 &= (1, -3, -3, -6) \end{aligned} .$$

$$\text{Row } A = \text{Span}\{\mathbf{r}_1, \mathbf{r}_2, \mathbf{r}_3\} \quad (\text{a subspace of } \mathbf{R}^4)$$

While it is natural to express row vectors horizontally, they can also be written as column vectors if it is more convenient. Therefore

$$\boxed{\text{Col } A^T = \text{Row } A} .$$

# Row Space and Row Equivalence

When we use row operations to reduce matrix  $A$  to matrix  $B$ , we are taking linear combinations of the rows of  $A$  to come up with  $B$ . We could reverse this process and use row operations on  $B$  to get back to  $A$ . Because of this, the row space of  $A$  equals the row space of  $B$ .

## Theorem (13)

*If two matrices  $A$  and  $B$  are row equivalent, then their row spaces are the same. If  $B$  is in echelon form, the nonzero rows of  $B$  form a basis for the row space of  $A$  as well as  $B$ .*

# Row Space: Example

## Example

The matrices

$$A = \begin{bmatrix} -1 & 2 & 3 & 6 \\ 2 & -5 & -6 & -12 \\ 1 & -3 & -3 & -6 \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} -1 & 2 & 3 & 6 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

are row equivalent. Find a basis for row space, column space and null space of  $A$ . Also state the dimension of each.

**Solution:** Basis for Row  $A$ :

$$\left\{ \right\}$$

dim Row  $A$  : \_\_\_\_\_

# Row Space: Example (cont.)

Basis for Col A:

$$\left\{ \begin{bmatrix} \phantom{0} \\ \phantom{0} \\ \phantom{0} \end{bmatrix}, \begin{bmatrix} \phantom{0} \\ \phantom{0} \\ \phantom{0} \end{bmatrix} \right\}$$

dim Col A :.....

To find Nul A, solve  $Ax = \mathbf{0}$  first:

$$\begin{bmatrix} -1 & 2 & 3 & 6 & 0 \\ 2 & -5 & -6 & -12 & 0 \\ 1 & -3 & -3 & -6 & 0 \end{bmatrix} \sim \begin{bmatrix} -1 & 2 & 3 & 6 & 0 \\ 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

$$\sim \begin{bmatrix} 1 & 0 & -3 & -6 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

# Row Space: Example (cont.)

$$\begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} = \begin{bmatrix} 3x_3 + 6x_4 \\ 0 \\ x_3 \\ x_4 \end{bmatrix} = x_3 \begin{bmatrix} 3 \\ 0 \\ 1 \\ 0 \end{bmatrix} + x_4 \begin{bmatrix} 6 \\ 0 \\ 0 \\ 1 \end{bmatrix}$$

Basis for Nul  $A$  :

$$\left\{ \begin{bmatrix} 3 \\ 0 \\ 1 \\ 0 \end{bmatrix}, \begin{bmatrix} 6 \\ 0 \\ 0 \\ 1 \end{bmatrix} \right\}$$

and  $\dim \text{Nul } A = \text{-----}$

# Rank: Definition

Note the following:

- $\dim \text{Col } A = \# \text{ of pivots of } A = \# \text{ of nonzero rows in } B = \dim \text{Row } A.$
- $\dim \text{Nul } A = \# \text{ of free variables} = \# \text{ of nonpivot columns of } A.$

## Rank

The **rank** of  $A$  is the dimension of the column space of  $A$ .

$$\text{rank } A = \dim \text{Col } A = \# \text{ of pivot columns of } A = \dim \text{Row } A.$$

# Rank Theorem

$$\underbrace{\text{rank } A}_{\substack{\updownarrow \\ \# \text{ of pivot} \\ \text{columns} \\ \text{of } A}} + \underbrace{\dim \text{Nul } A}_{\substack{\updownarrow \\ \# \text{ of nonpivot} \\ \text{columns} \\ \text{of } A}} = \underbrace{n}_{\substack{\updownarrow \\ \# \text{ of} \\ \text{columns} \\ \text{of } A}}$$

## Theorem (14 Rank Theorem)

*The dimensions of the column space and the row space of an  $m \times n$  matrix  $A$  are equal. This common dimension, the rank of  $A$ , also equals the number of pivot positions in  $A$  and satisfies the equation*

$$\text{rank } A + \dim \text{Nul } A = n.$$

# Rank Theorem: Example

Since  $\text{Row } A = \text{Col } A^T$ ,  $\boxed{\text{rank } A = \text{rank } A^T}$ .

## Example

Suppose that a  $5 \times 8$  matrix  $A$  has rank 5. Find  $\dim \text{Nul } A$ ,  $\dim \text{Row } A$  and  $\text{rank } A^T$ . Is  $\text{Col } A = \mathbf{R}^5$ ?

### Solution:

$$\begin{array}{ccc}
 \underbrace{\text{rank } A}_{\begin{array}{c} \updownarrow \\ 5 \end{array}} + \underbrace{\dim \text{Nul } A}_{\begin{array}{c} \downarrow \\ ? \end{array}} = \underbrace{n}_{\begin{array}{c} \updownarrow \\ 8 \end{array}} \\
 5 + \dim \text{Nul } A = 8 \quad \Rightarrow \quad \dim \text{Nul } A = \text{-----} \\
 \dim \text{Row } A = \text{rank } A = \text{-----} \\
 \Rightarrow \quad \text{rank } A^T = \text{rank } \text{-----} = \text{-----}
 \end{array}$$

Since  $\text{rank } A = \#$  of pivots in  $A = 5$ , there is a pivot in every row. So the columns of  $A$  span  $\mathbf{R}^5$  (by Theorem 4, page 43). Hence  $\text{Col } A = \mathbf{R}^5$ .

# Rank Theorem: Example

## Example

For a  $9 \times 12$  matrix  $A$ , find the smallest possible value of  $\dim \text{Nul } A$ .

**Solution:**

$$\text{rank } A + \dim \text{Nul } A = 12$$

$$\dim \text{Nul } A = 12 - \underbrace{\text{rank } A}_{\text{largest possible value} = \dots}$$

smallest possible value of  $\dim \text{Nul } A = \dots$

# Visualizing Row $A$ and Nul $A$

## Example

Let  $A = \begin{bmatrix} 1 & 0 & -1 \\ 2 & 0 & 2 \end{bmatrix}$ . One can easily verify the following:

1. Basis for Nul  $A = \left\{ \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}, \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix} \right\}$  and Nul  $A$  is a plane in  $\mathbf{R}^3$ .
2. Basis for Row  $A = \left\{ \begin{bmatrix} 1 \\ 0 \\ -1 \end{bmatrix} \right\}$  and Row  $A$  is a line in  $\mathbf{R}^3$ .
3. Basis for Col  $A = \left\{ \begin{bmatrix} 1 \\ 2 \end{bmatrix} \right\}$  and Col  $A$  is a line in  $\mathbf{R}^2$ .
4. Basis for Nul  $A^T = \left\{ \begin{bmatrix} -2 \\ 1 \end{bmatrix} \right\}$  and Nul  $A^T$  is a line in  $\mathbf{R}^2$ .

## Rank Theorem: Example (cont.)

Subspaces  $\text{Nul } A$  and  $\text{Row } A$ Subspaces  $\text{Nul } A^T$  and  $\text{Col } A$ 

# Rank Theorem: Example

The Rank Theorem provides us with a powerful tool for determining information about a system of equations.

## Example

A scientist solves a homogeneous system of 50 equations in 54 variables and finds that exactly 4 of the unknowns are free variables. Can the scientist be *certain* that any associated nonhomogeneous system (with the same coefficients) has a solution?

**Solution:** Recall that

- $\text{rank } A = \dim \text{Col } A = \#$  of pivot columns of  $A$
- $\dim \text{Nul } A = \#$  of free variables

# Rank Theorem: Example (cont.)

In this case  $A\mathbf{x} = \mathbf{0}$  of where  $A$  is  $50 \times 54$ .

By the rank theorem,

$$\text{rank } A + \text{nullity } A = \text{number of columns}$$

or

$$\text{rank } A = \text{number of columns} - \text{nullity } A$$

So any nonhomogeneous system  $A\mathbf{x} = \mathbf{b}$  has a solution because there is a pivot in every row.

# The Invertible Matrix Theorem (continued)

## Theorem (Invertible Matrix Theorem (continued))

Let  $A$  be a square  $n \times n$  matrix. The the following statements are equivalent:

- m. The columns of  $A$  form a basis for  $\mathbf{R}^n$
- n.  $\text{Col } A = \mathbf{R}^n$
- o.  $\dim \text{Col } A = n$
- p.  $\text{rank } A = n$
- q.  $\text{Nul } A = \{\mathbf{0}\}$
- r.  $\dim \text{Nul } A = 0$
