Modeling Nearly Exponential Data: Exponential Regression

When we looked at linear data, we saw that often the data were not perfectly linear, but we could still model the data using a linear function.
Similarly, sometimes data is not exactly exponential, but we can still use an exponential function to model the data.

## Graphs of Exponential Function

The graph of an exponential function $f(x)=P a^{x}$ has one of two forms (depending on whether it is exponential growth or decay).

$a<1$ : exponential decay

The graphs of exponential functions are always concave up and either always increasing or always decreasing.

If the scatter plot of a data set shows either of these "shapes", then an exponential regression model is likely appropriate.

Example 1: This data gives US population in millions from 1800 to 1860:

| Date | 1800 | 1810 | 1820 | 1830 | 1840 | 1850 | 1860 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Population | 5.31 | 7.24 | 9.64 | 12.87 | 17.07 | 23.19 | 31.44 |

Graph the data and answer this question: Is it reasonable to approximate the data with an exponential model?

Use the exponential regression feature of the statistical calculator to find the initial value and the growth factor of the linear regression model for this data. Then write an exponential function that models this data.

Use the model to approximate the population in 1870.

Use the model to determine the approximate year when the population crossed 50 million people

Example 2: Use the data given in the table below to find an exponential regression model that fits the data.

| $\boldsymbol{x}$ | 4.2 | 7.9 | 10.8 | 15.5 | 20.2 |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\boldsymbol{y}$ | 7.5 | 8.1 | 8.5 | 10.2 | 12.3 |

Use the model to find the value when $x=12$.

Use the model to find the value of $x$ for which the model equals 9 .

Example 3: The table below shows the number of cell phone subscribers (in millions) in the US at the end of the given year.

| Year | 2001 | 2002 | 2003 | 2004 | 2005 |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Subscribers | 128.4 | 140.8 | 158.7 | 182.1 | 207.9 |

Plot the data points. Is it reasonable to approximate the date using an exponential model?

Use exponential regression to construct an exponential model for the data.

Graph the exponential regression model with the data points.

What was the yearly percentage growth rate from the end of 2001 through the end of 2005 ?

Would this model support this statement (made in 2005): "By the end of 2007, there will be 250 million cell phone subscribers in the US."

Using this model, in what year would you expect cell phone subscribership to reach 275 million?
