Section 8.5

Goodness of Fit Test

Suppose we want to make an inference about a group of data (instead of just one or two). Or maybe we want to test counts of categorical data. Chi-square (or χ^2) testing allows us to make such inferences.

There are several types of Chi-square tests but in this section we will focus on the goodness-of-fit test. **Goodness-of-fit** test is used to test how well one sample proportions of categories "match-up" with the known population proportions stated in the null hypothesis statement. The Chi-square goodness-of-fit test extends inference on proportions to more than two proportions by enabling us to determine if a particular population distribution has changed from a specified form.

The null and alternative hypotheses do not lend themselves to symbols, so we will define them with words.

 H_{o} : ____ is the same as ____ H_{a} : ____ is different from ____

For each problem you will make a table with the following headings:

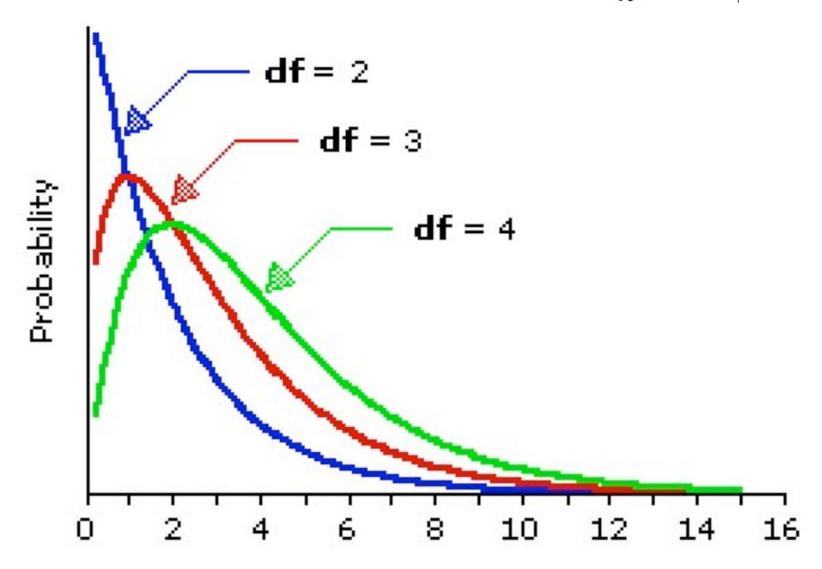

Observed Counts (O) Expected Counts (E)
$$(O-E)^2$$

The sum of the third column is called the Chi-square test statistic.

$$\chi^2 = \sum \frac{\text{(observed - expected)}^2}{\text{expected}}$$

Table D gives p-values for χ^2 with n-1 degrees of freedom.

Chi-square distributions have only positive values and are skewed right. As the degrees of freedom increase it becomes more normal. The total area under the χ^2 curve is 1.

The assumptions for a Chi-square goodness-of-fit test are:

- 1. The sample must be an SRS from the populations of interest.
- 2. The population size is at least ten times the size of the sample.
- 3. All expected counts must be at least 5.

To find probabilities for χ^2 distributions:

TI-83/84 calculator uses the command χ^2 cdf found under the DISTR menu.

R-Studio command is: 1 – pchisq(test statistic, df)

Example:

1. The Mixed-Up Nut Company advertises that their nut mix contains (by weight) 40% cashews, 15% Brazil nuts, 20% almonds and only 25% peanuts. The truth-in-advertising investigators took a random sample (of size 50 lbs) of the nut mix and found the distribution to be as follows:

Cashews	Brazil Nuts	Almonds	Peanuts
15 lb	11 lb	13 lb	11 lb

At the 1% level of significance, is the claim made by Mixed-Up Nuts true?

Another Example:

Suppose you rolled a die 60 times and observed 14 ones, 8 twos, 7 threes, 16 fours, 7 fives, and 8 sixes. Is this a fair die?

Test the claim at the 5% significance level.
