

## Early Definitions and Postulates (1.3)

### Four Parts of a Mathematical System

1. Undefined terms
2. Defined terms
3. Axioms or postulates
4. Theorems

**Definition:** An \_\_\_\_\_ triangle is a triangle that has two congruent sides.

### Characteristics of a good definition:

1. It names the term being defined.
2. It places the term into a set or category.
3. It distinguishes the defined term from other terms without providing unnecessary facts.
4. It is reversible.

**Definition:** A \_\_\_\_\_ is the part of the line that consists of two points, known as endpoints and all points between them.

**Postulate 1:** Through two distinct points, there is exactly one \_\_\_\_\_.

**Postulate 2:** The measurement of any line segment is a unique number. (\_\_\_\_\_ Postulate)

**Definition:** The distance between two points A and B is the \_\_\_\_\_ of the line segment  $\overline{AB}$  that joins the points.

**Postulate 3:** If X is a point on  $\overline{AB}$  and  $A - X - B$  then  $AX + XB = AB$

**Definition:** Congruent ( $\cong$ ) line segments are two lines that have the same \_\_\_\_\_.

**Definition:** The \_\_\_\_\_ of a line segment is the point that separates the line segment into two congruent parts.

**Example 1:** Given M is the midpoint of  $\overline{AB}$ ,  $AM = 3(x + 3)$  and  $MB = 4(x - 2)$ . Find the length of  $\overline{AB}$  and the value for x.

**Definition:** Ray AB denoted by  $\overrightarrow{AB}$ , is the union of  $\overline{AB}$  and all points X on  $\overleftrightarrow{AB}$  such that B is between A and X.

**Postulate 4:** If two lines intersect, they intersect at a \_\_\_\_\_.

**Definition:** Parallel lines are lines that lie in the same plane but do \_\_\_\_\_ intersect.

**Postulate 5:** Through three noncollinear points, there is exactly one \_\_\_\_\_.

**Postulate 6:** If two distinct planes intersect, then their intersection is a \_\_\_\_\_.

**Postulate 7:** Given two distinct points in a plane, the line containing these points also lies in that plane.

**Theorem 1.3.1:** The midpoint of a line is \_\_\_\_\_.

### Angles and Their Relationships (1.4)

**Definition:** An angle is the union of two rays that share a common \_\_\_\_\_.

**Postulate 8:** The measurement of an angle is a unique positive number.

**Postulate 9:** If a point D lies in the interior of an angle ABC, then  $\angle ABD + \angle DBC = \angle ABC$

**Example 2:** Given:  $m\angle ABD = 2x + 5$

$$m\angle DBC = 3x - 4$$

$$m\angle ABC = 86^\circ$$

Find  $m\angle DBC$

**Definition:** Two angles are \_\_\_\_\_ (adj.  $\angle$ s) if they have a common vertex and a common side between them. (Check-out the last example).

**Definition:** \_\_\_\_\_ angles ( $\cong \angle$ s) are two angles of the same measure.

**Definition:** The \_\_\_\_\_ of an angle is the ray that separates the given angle into two congruent angles.

**Example 3:** Given:  $\overrightarrow{BD}$  bisects  $\angle ABC$

$$m\angle ABD = x + y$$

$$m\angle DBC = 2x - 2y$$

$$m\angle ABC = 64^\circ \quad \text{find } x \text{ and } y$$

**Definition:** \_\_\_\_\_ **Angles** - is where two straight lines intersect, the pairs of nonadjacent angles formed are vertical angles. Vertical angles are congruent. The two adjacent angles are supplementary.

**Example 4:** Use the figure from above.

- a. If  $m\angle 4 = 97^\circ$ , find the measures of the other 3 angles.
  
  
  
  
  
  
  
  
  
  
- b. If  $m\angle 1 = x + 7$  and the  $m\angle 2 = 2x - 23$ , find  $x$  and the measures of four angles.

**Example 5:** Use the figure to answer each questions.

Find the measure of all the angles 1 -7.

Hint:  $m\angle 3 + m\angle 5 + m\angle 6 = 180^\circ$
