## Motivation: seismic oil and gas exploration

- Seismic exploration

- Seismic waves in the subsurface induced by sources (shots)
- Measurements of seismic signals on the surface or in a well bore
- Determine the acoustic or elastic parameters of the subsurface

## Forward model: acoustic wave equation

- Consider an acoustic wave equation in the time domain

$$
u_{t t}=\mathbf{A} u \quad \text { in } \Omega, \quad t \in[0, T]
$$

with initial conditions

$$
\left.u\right|_{t=0}=u_{0},\left.\quad u_{t}\right|_{t=0}=0
$$

- The spatial operator $\mathbf{A} \in \mathbb{R}^{N \times N}$ is a fine grid discretization of

$$
A(c)=c^{2} \Delta
$$

with the appropriate boundary conditions

- The solution is

$$
u(t)=\cos (t \sqrt{-\mathbf{A}}) u_{0}
$$

## Source model

- We stack all $p$ sources in a single tall skinny matrix $\mathbf{S} \in \mathbb{R}^{N \times p}$ and introduce them in the initial condition

$$
\left.\mathbf{u}\right|_{t=0}=\mathbf{S},\left.\quad \mathbf{u}_{t}\right|_{t=0}=0
$$

- The solution matrix $\mathbf{u}(t) \in \mathbb{R}^{N \times p}$ is

$$
\mathbf{u}(t)=\cos (t \sqrt{-\mathbf{A}}) \mathbf{S}
$$

- We assume the form of the source matrix

$$
\mathbf{S}=q^{2}(\mathbf{A}) \mathbf{C E}
$$

where $p$ columns of $\mathbf{E}$ are point sources on the surface, $q^{2}(\omega)$ is the Fourier transform of the source wavelet and $\mathbf{C}=\operatorname{diag}(c)$

- Here we take $q^{2}(\omega)=e^{\sigma \omega}$ with small $\sigma$ so that $\mathbf{S}$ is localized near E

## Receiver and data model

- For simplicity assume that the sources and receivers are collocated
- Then the receiver matrix $\mathbf{R} \in \mathbb{R}^{N \times p}$ is

$$
\mathbf{R}=\mathbf{C}^{-1} \mathbf{E}
$$

- Combining the source and receiver we get the data model

$$
\mathbf{F}(t ; c)=\mathbf{R}^{T} \cos (t \sqrt{-\mathbf{A}(c)}) \mathbf{S}
$$

a $p \times p$ matrix function of time

- The data model can be fully symmetrized

$$
\mathbf{F}(t)=\mathbf{B}^{T} \cos (t \sqrt{-\widehat{\mathbf{A}}}) \mathbf{B}
$$

with $\widehat{\mathbf{A}}=\mathbf{C} \boldsymbol{\Delta} \mathbf{C}$ and $\mathbf{B}=q(\widehat{\mathbf{A}}) \mathbf{E}$

## Seismic inversion and imaging

(1) Seismic inversion: determine $c$ from the knowledge of measured data $\mathbf{F}^{\star}(t)$ (full waveform inversion, FWI ); highly nonlinear since $\mathbf{F}(\cdot ; c)$ is nonlinear in $c$

- Conventional approach: non-linear least squares (output least squares, OLS)

$$
\underset{c}{\operatorname{minimize}}\left\|\mathbf{F}^{\star}-\mathbf{F}(\cdot ; c)\right\|_{2}^{2}
$$

- Abundant local minima
- Slow convergence
- Low frequency data needed
(2) Seismic imaging: estimate $c$ or its discontinuities given $\mathbf{F}(t)$ and also a smooth kinematic model $c_{0}$
- Conventional approach: linear migration (Kirchhoff, reverse time migration - RTM)
- Major difficulty: multiple reflections

## Reduced order models

- The data is always discretely sampled, say uniformly at $t_{k}=k \tau$
- The choice of $\tau$ is very important, optimally we want $\tau$ around Nyquist rate
- The discrete data samples are

$$
\begin{aligned}
\mathbf{F}_{k} & =\mathbf{F}(k \tau)=\mathbf{B}^{T} \cos (k \tau \sqrt{-\widehat{\mathbf{A}}}) \mathbf{B}= \\
& =\mathbf{B}^{T} \cos (k \arccos (\cos \tau \sqrt{-\widehat{\mathbf{A}}})) \mathbf{B}=\mathbf{B}^{T} T_{k}(\mathbf{P}) \mathbf{B}
\end{aligned}
$$

where $T_{k}$ is Chebyshev polynomial and the propagator is

$$
\mathbf{P}=\cos (\tau \sqrt{-\widehat{\mathbf{A}}})
$$

- We want a reduced order model (ROM) $\widetilde{\mathbf{P}}, \widetilde{\mathbf{B}}$ that fits the measured data

$$
\mathbf{F}_{k}=\mathbf{B}^{T} T_{k}(\mathbf{P}) \mathbf{B}=\widetilde{\mathbf{B}}^{T} T_{k}(\widetilde{\mathbf{P}}) \widetilde{\mathbf{B}}, \quad k=0,1, \ldots, 2 n-1
$$

## Projection ROMs

- Projection ROMs are obtained from

$$
\widetilde{\mathbf{P}}=\mathbf{V}^{\top} \mathbf{P V}, \quad \widetilde{\mathbf{B}}=\mathbf{V}^{\top} \mathbf{B}
$$

where $\mathbf{V}$ is an orthonormal basis for some subspace

- How do we get a ROM that fits the data?
- Consider a matrix of solution snapshots

$$
\mathbf{U}=\left[\mathbf{u}_{0}, \mathbf{u}_{1}, \ldots, \mathbf{u}_{n-1}\right] \in \mathbb{R}^{N \times n p}, \quad \mathbf{u}_{k}=T_{k}(\mathbf{P}) \mathbf{B}
$$

## Theorem (ROM data interpolation)

If $\operatorname{span}(\mathbf{V})=\operatorname{span}(\mathbf{U})$ and $\mathbf{V}^{\top} \mathbf{V}=\mathbf{I}$ then

$$
\mathbf{F}_{k}=\mathbf{B}^{T} T_{k}(\mathbf{P}) \mathbf{B}=\widetilde{\mathbf{B}}^{T} T_{k}(\widetilde{\mathbf{P}}) \widetilde{\mathbf{B}}, \quad k=0,1, \ldots, 2 n-1
$$

where $\widetilde{\mathbf{P}}=\mathbf{V}^{\top} \mathbf{P V} \in \mathbb{R}^{n p \times n p}$ and $\widetilde{\mathbf{B}}=\mathbf{V}^{\top} \mathbf{B} \in \mathbb{R}^{n p \times p}$.

## ROM from measured data

- We do not know the solutions in the whole domain $\mathbf{U}$ and thus $\mathbf{V}$ is unknown
- How do we obtain the ROM from just the data $\mathbf{F}_{k}$ ?
- The data does not give us $\mathbf{U}$, but it gives us the inner products!
- A basic property of Chebyshev polynomials is

$$
T_{i}(x) T_{j}(x)=\frac{1}{2}\left(T_{i+j}(x)+T_{|i-j|}(x)\right)
$$

- Then we can obtain

$$
\begin{aligned}
\left(\mathbf{U}^{T} \mathbf{U}\right)_{i, j} & =\mathbf{u}_{i}^{T} \mathbf{u}_{j}=\frac{1}{2}\left(\mathbf{F}_{i+j}+\mathbf{F}_{i-j}\right), \\
\left(\mathbf{U}^{T} \mathbf{P} \mathbf{U}\right)_{i, j} & =\mathbf{u}_{i}^{T} \mathbf{P} \mathbf{u}_{j}=\frac{1}{4}\left(\mathbf{F}_{j+i+1}+\mathbf{F}_{j-i+1}+\mathbf{F}_{j+i-1}+\mathbf{F}_{j-i-1}\right)
\end{aligned}
$$

## ROM from measured data

- Suppose $\mathbf{U}$ is orthogonalized by a block QR (Gram-Schmidt) procedure

$$
\mathbf{U}=\mathbf{V L}^{T} \text {, equivalently } \mathbf{V}=\mathbf{U L}^{-T}
$$

where $\mathbf{L}$ is a block Cholesky factor of the Gramian $\mathbf{U}^{\top} \mathbf{U}$ known from the data

$$
\mathbf{U}^{T} \mathbf{U}=\mathbf{L L}^{T}
$$

- The projection is given by

$$
\widetilde{\mathbf{P}}=\mathbf{V}^{T} \mathbf{P} \mathbf{V}=\mathbf{L}^{-1}\left(\mathbf{U}^{T} \mathbf{P} \mathbf{U}\right) \mathbf{L}^{-T}
$$

where $\mathbf{U}^{T} \mathbf{P U}$ is also known from the data

- The use of Cholesky for orthogonalization is essential, (block) lower triangular structure is the linear algebraic equivalent of causality

## Image from the ROM

- How to extract an image form the ROM?
- ROM is a projection, we can use backprojection
- If $\operatorname{span}(\mathbf{U})$ is suffiently rich, then columns of $\mathbf{V} \mathbf{V}^{T}$ should be good approximations of $\delta$-functions, hence

$$
\mathbf{P} \approx \mathbf{V} \mathbf{V}^{T} \mathbf{P} \mathbf{V} \mathbf{V}^{T}=\mathbf{V} \widetilde{\mathbf{P}} \mathbf{V}^{T}
$$

- Problem: snapshots $\mathbf{U}$ in the whole domain are unknown, so are orthogonalized snapshots V
- In imaging we have a rough idea of kinematics, i.e. we know approximately the travel times
- This is equivalent to knowing a kinematic model, a smooth non-reflective sound speed $c_{0}$
- Once $c_{0}$ is fixed, we know everything associated with it

$$
\widehat{\mathbf{A}}_{0}, \quad \mathbf{P}_{0}, \quad \mathbf{U}_{0}, \quad \mathbf{V}_{0}, \quad \widetilde{\mathbf{P}}_{0}
$$

## Approximate backprojection

- We take the backprojection $\mathbf{P} \approx \mathbf{V} \widetilde{\mathbf{P}} \mathbf{V}^{\top}$ and make another approximation replacing unknown $\mathbf{V}$ with the kinematic model basis $\mathbf{V}_{0}$ :

$$
\mathbf{P} \approx \mathbf{V}_{0} \widetilde{\mathbf{P}} \mathbf{V}_{0}^{T}
$$

- For the kinematic model we know the basis exactly

$$
\mathbf{P}_{0} \approx \mathbf{V}_{0} \widetilde{\mathbf{P}}_{0} \mathbf{V}_{0}^{T}
$$

- If $\delta_{x}$ is a $\delta$-function centered at point $x$, then

$$
\mathbf{P} \delta_{x}=\cos (\tau \sqrt{-\widehat{\mathbf{A}}}) \delta_{x}=w(\tau)
$$

where $w(t)$ is a solution to

$$
w_{t t}=\widehat{\mathbf{A}} w, \quad w(0)=\delta_{x}, \quad w_{t}(0)=0
$$

i.e. it is a Green's function $G(x, \cdot, \tau)$

## Green's function and imaging

- Diagonal entries of $\mathbf{P}$ are Green's function evaluated at the same point

$$
G(x, x, \tau)=\delta_{x}^{T} \mathbf{P} \delta_{x}
$$

- By taking the diagonals of backprojections we may extract the approximate Green's functions
$G(\cdot, \cdot, \tau)-G_{0}(\cdot, \cdot, \tau)=\operatorname{diag}\left(\mathbf{P}-\mathbf{P}_{0}\right) \approx \operatorname{diag}\left(\mathbf{V}_{0}\left(\widetilde{\mathbf{P}}-\widetilde{\mathbf{P}}_{0}\right) \mathbf{V}_{0}^{T}\right)=\mathcal{I}$
- Approximation quality depends only on how well columns of $\mathbf{V V}_{0}^{T}$ and $\mathbf{V}_{0} \mathbf{V}_{0}^{T}$ approximate $\delta$-functions
- It appears that $\mathcal{I}$ works well as an imaging functional to image the discontinuities of $c$
- Despite the name "backprojection" our method is nonlinear in the data since obtaining $\widetilde{\mathbf{P}}$ from $\mathbf{F}_{k}$ is a nonlinear procedure (block Lanczos and matrix inversion)

## Simple example: layered model

True sound speed $c$

 sources/receivers (black $\times$ )

- Constant velocity kinematic model $c_{0}=1500 \mathrm{~m} / \mathrm{s}$
- Multiple reflections from waves bouncing between layers and surface
- Each multiple creates an RTM artifact below actual layers

Backprojection: $c_{0}+\alpha \mathcal{I}$

RTM image

## Why ROM backprojection imaging works?

- Suppression of multiples: implicit causal orhthogonalization (block Gram-Schmidt) of snapshots $\mathbf{U}$ removes the "tail" with reflections and produces a focused, localized pulse
- Compare $\mathbf{U}$ and $\mathbf{V}$ for various times
- Approximation

$$
G(\cdot, \cdot, \tau)-G_{0}(\cdot, \cdot, \tau) \approx \operatorname{diag}\left(\mathbf{V}_{0}\left(\widetilde{\mathbf{P}}-\widetilde{\mathbf{P}}_{0}\right) \mathbf{V}_{0}^{T}\right)
$$

only works if columns of $\mathbf{V} \mathbf{V}_{0}^{T}$ and $\mathbf{V}_{0} \mathbf{V}_{0}^{T}$ are good approximations of $\delta$-functions

- Plot columns of $\mathbf{V} \mathbf{V}_{0}^{T}$ and $\mathbf{V}_{0} \mathbf{V}_{0}^{T}$ for various points in the domain
- ROM computation resolves the dynamics fully, so image imperfections are mostly due to deficiencies of the kinematic model

## Snapshot orthogonalization

Snapshots U

Orthogonalized snapshots V

## Snapshot orthogonalization

Snapshots U

Orthogonalized snapshots V

$$
t=25 \tau
$$

$$
t=30 \tau
$$

$$
t=35 \tau
$$

## Approximation of $\delta$-functions

$\begin{array}{lllllllll}0.3 & 0.6 & 0.9 & 1.2 & 1.5 & 1.8 & 2.1 & 2.4 & 2.7\end{array}$

$y=345 m$
$y=510 m$
$y=675 m$

## Approximation of $\delta$-functions

## Columns of $\mathbf{V}_{0} \mathbf{V}_{0}^{T}$

Columns of $\mathbf{V V}_{0}^{T}$

$y=840 m$
$\begin{array}{lllllllll}0.3 & 0.6 & 0.9 & 1.2 & 1.5 & 1.8 & 2.1 & 2.4 & 2.7\end{array}$

$y=1020 m$
$y=1185 m$

TiT

## High contrast example: hydraulic fractures

True $c$

Backprojection image $\mathcal{I}$

- Important application: acoustic monitoring of hydraulic fracturing
- Multiple thin fractures (down to 1 cm in width, here 10 cm )
- Very high contrasts: $c=4500 \mathrm{~m} / \mathrm{s}$ in the surrounding rock, $c=1500 \mathrm{~m} / \mathrm{s}$ in the fluid inside fractures

## High contrast example: hydraulic fractures

True $c$

RTM image

- Important application: acoustic monitoring of hydraulic fracturing
- Multiple thin fractures (down to 1 cm in width, here 10 cm )
- Very high contrasts: $c=4500 \mathrm{~m} / \mathrm{s}$ in the surrounding rock, $c=1500 \mathrm{~m} / \mathrm{s}$ in the fluid inside fractures

## Large scale example: Marmousi model

- Standard Marmousi model, $13.5 \mathrm{~km} \times 2.7 \mathrm{~km}$
- Forward problem is discretized on a 15 m grid with $N=900 \times 180=162,000$ nodes
- Kinematic model $c_{0}$ : smoothed out true c (465m horizontally, 315 m vertically)
- Time domain data sample rate $\tau=33.5 \mathrm{~ms}$, source frequency about $15 \mathrm{~Hz}, n=35$ data samples measured
- Number of sources/receivers $p=90$ uniformly distributed with spacing 150 m
- Data is split into 17 overlapping windows of 10 sources/receivers each (1.5km max offset)
- Reflecting boundary conditions
- No data filtering, everything used as is (surface wave, reflections from the boundaries, multiples)

Backprojection imaging

## Other possible applications: ultrasound tomography

True $c$

Backprojection image

- Ultrasound screening for early detection of breast cancer
- Conventional ultrasound imaging techniques are rather crude, advanced methods originating in geophysics are in demand

## Conclusions and future work

- Novel approach to acoustic imaging using reduced order models
- Time domain formulation is essential, makes use of causality (linear algebraic analogues - Gram-Schmidt, Cholesky decomposition)
- Nonlinear imaging: strong suppression of multiple reflection artifacts; improved resolution compared to RTM

## Future work:

- Non-symmetric forward model and ROM for non-collocated sources/receivers
- Better theoretical understanding, relation of $\mathcal{I}$ to $c$
- Use for ROMs for full waveform inversion
