# Nonlinear seismic imaging via reduced order model backprojection 

Alexander V. Mamonov ${ }^{1}$,<br>Vladimir Druskin ${ }^{2}$ and Mikhail Zaslavsky ${ }^{2}$

${ }^{1}$ University of Houston,<br>${ }^{2}$ Schlumberger-Doll Research Center

## Motivation: seismic oil and gas exploration

- Seismic exploration

- Seismic waves in the subsurface induced by sources (shots)
- Measurements of seismic signals on the surface or in a well bore
- Determine the acoustic or elastic parameters of the subsurface

## Acoustic wave equation

- Consider an acoustic wave equation in the time domain

$$
u_{t t}=\mathbf{A} u \quad \text { in } \Omega, \quad t \in[0, T]
$$

with initial conditions

$$
\left.u\right|_{t=0}=u_{0},\left.\quad u_{t}\right|_{t=0}=0
$$

- The spatial operator $\mathbf{A} \in \mathbb{R}^{N \times N}$ is a fine grid discretization of

$$
A(c)=c^{2} \Delta
$$

with the appropriate boundary conditions

- The solution is

$$
u(t)=\cos (t \sqrt{-\mathbf{A}}) u_{0}
$$

## Source model

- We stack all $p$ sources in a single tall skinny matrix $\mathbf{S} \in \mathbb{R}^{N \times p}$ and introduce them in the initial condition

$$
\left.\mathbf{u}\right|_{t=0}=\mathbf{S},\left.\quad \mathbf{u}_{t}\right|_{t=0}=0
$$

- The solution matrix $\mathbf{u}(t) \in \mathbb{R}^{N \times p}$ is

$$
\mathbf{u}(t)=\cos (t \sqrt{-\mathbf{A}}) \mathbf{S}
$$

- We assume the form of the source matrix

$$
\mathbf{S}=q^{2}(\mathbf{A}) \mathbf{C E}
$$

where $\mathbf{E}$ are $p$ point sources supported on the surface, $q^{2}(\omega)$ is the Fourier transform of the source wavelet and $\mathbf{C}=\operatorname{diag}(\mathbf{c})$

- Here we take $q^{2}(\omega)=e^{\sigma \omega}$ with small $\sigma$ so that $\mathbf{S}$ is localized near $\mathbf{E}$, only assumes the knowledge of $\mathbf{c}$ and thus $\mathbf{A}$ near the surface

## Receiver and data model

- For simplicity assume that the sources and receivers are collocated
- Then the receiver matrix $\mathbf{R} \in \mathbb{R}^{N \times p}$ is

$$
\mathbf{R}=\mathbf{C}^{-1} \mathbf{E}
$$

- Combining the source and receiver we get the data model

$$
\mathbf{F}(t ; \mathbf{c})=\mathbf{R}^{T} \cos (t \sqrt{-\mathbf{A}(\mathbf{c})}) \mathbf{S}
$$

a $p \times p$ matrix function of time

- The data model can be fully symmetrized

$$
\mathbf{F}(t)=\widehat{\mathbf{B}}^{T} \cos (t \sqrt{-\widehat{\mathbf{A}}}) \widehat{\mathbf{B}}
$$

with $\widehat{\mathbf{A}}=\mathbf{C} \boldsymbol{\Delta} \mathbf{C}$ and $\widehat{\mathbf{B}}=q(\widehat{\mathbf{A}}) \mathbf{E}$

## Seismic inversion and imaging

(1) Seismic inversion: determine c from the knowledge of measured data $\mathbf{F}^{\star}(t)$ (full waveform inversion, FWI ); highly nonlinear since $\mathbf{F}(\cdot ; \mathbf{c})$ is nonlinear in $\mathbf{c}$

- Conventional approach: non-linear least squares (output least squares, OLS)

$$
\underset{\mathbf{c}}{\operatorname{minimize}}\left\|\mathbf{F}^{\star}-\mathbf{F}(\cdot ; \mathbf{c})\right\|_{2}^{2}
$$

- Abundant local minima
- Slow convergence
- Low frequency data needed
(2) Seismic imaging: estimate $\mathbf{c}$ or its discontinuities given $\mathbf{F}(t)$ and also a smooth kinematic model $\mathbf{c}_{0}$
- Conventional approach: linear migration (Kirchhoff, reverse time migration - RTM)
- Major difficulty: multiple reflections

## Reduced order models

- The data is always discretely sampled, say uniformly at $t_{k}=k \tau$
- The choice of $\tau$ is very important, optimally we want $\tau$ around Nyquist rate
- The discrete data samples are

$$
\begin{aligned}
\mathbf{F}_{k} & =\mathbf{F}(k \tau)=\widehat{\mathbf{B}}^{T} \cos (k \tau \sqrt{-\widehat{\mathbf{A}}}) \widehat{\mathbf{B}}= \\
& =\widehat{\mathbf{B}}^{T} \cos (k \arccos (\cos \tau \sqrt{-\widehat{\mathbf{A}}})) \widehat{\mathbf{B}}=\widehat{\mathbf{B}}^{T} T_{k}(\widehat{\mathbf{P}}) \widehat{\mathbf{B}}
\end{aligned}
$$

where $T_{k}$ is Chebyshev polynomial and the propagator is

$$
\widehat{\mathbf{P}}=\cos (\tau \sqrt{-\widehat{\mathbf{A}}})
$$

- We want a reduced order model (ROM) $\widetilde{\mathbf{P}}, \widetilde{\mathbf{B}}$ that fits the measured data

$$
\mathbf{F}_{k}=\widehat{\mathbf{B}}^{T} T_{k}(\widehat{\mathbf{P}}) \widehat{\mathbf{B}}=\widetilde{\mathbf{B}}^{T} T_{k}(\widetilde{\mathbf{P}}) \widetilde{\mathbf{B}}, \quad k=0, \ldots, 2 n-1
$$

## Projection ROMs

- Projection ROMs are obtained from

$$
\widetilde{\mathbf{P}}=\mathbf{V}^{\top} \widehat{\mathbf{P}} \mathbf{V}, \quad \widetilde{\mathbf{B}}=\mathbf{V}^{\top} \widehat{\mathbf{B}}
$$

where $\mathbf{V}$ is an orthonormal basis for some subspace

- How do we get a ROM that fits the data?
- Consider a matrix of solution snapshots

$$
\mathbf{U}=\left[\widehat{\mathbf{u}}_{0}, \widehat{\mathbf{u}}_{1}, \ldots, \widehat{\mathbf{u}}_{n-1}\right] \in \mathbb{R}^{N \times n p}, \quad \widehat{\mathbf{u}}_{k}=T_{k}(\widehat{\mathbf{P}}) \widehat{\mathbf{B}}
$$

## Theorem (ROM data interpolation)

If $\operatorname{span}(\mathbf{V})=\operatorname{span}(\mathbf{U})$ and $\mathbf{V}^{\top} \mathbf{V}=\mathbf{I}$ then

$$
\mathbf{F}_{k}=\widehat{\mathbf{B}}^{T} T_{k}(\widehat{\mathbf{P}}) \widehat{\mathbf{B}}=\widetilde{\mathbf{B}}^{T} T_{k}(\widetilde{\mathbf{P}}) \widetilde{\mathbf{B}}, \quad k=1, \ldots, 2 n-1
$$

where $\widetilde{\mathbf{P}}=\mathbf{V}^{\top} \widehat{\mathbf{P}} \mathbf{V} \in \mathbb{R}^{n p \times n p}$ and $\widetilde{\mathbf{B}}=\mathbf{V}^{\top} \widehat{\mathbf{B}} \in \mathbb{R}^{n p \times p}$.

## Obtaining the ROM from the data

- We do not know the solutions in the whole domain $\mathbf{U}$ and thus $\mathbf{V}$ is unknown
- How do we obtain the ROM from just the data $\mathbf{F}_{k}$ ?
- The data does not give us $\mathbf{U}$, but it gives us the inner products!
- A basic property of Chebyshev polynomials is

$$
T_{i}(x) T_{j}(x)=\frac{1}{2}\left(T_{i+j}(x)+T_{|i-j|}(x)\right)
$$

- Then we can obtain

$$
\begin{aligned}
\left(\mathbf{U}^{T} \mathbf{U}\right)_{i, j} & =\mathbf{u}_{i}^{T} \mathbf{u}_{j}=\frac{1}{2}\left(\mathbf{F}_{i+j}+\mathbf{F}_{i-j}\right), \\
\left(\mathbf{U}^{T} \widehat{\mathbf{P}} \mathbf{U}\right)_{i, j} & =\mathbf{u}_{i}^{T} \widehat{\mathbf{P}} \mathbf{u}_{j}=\frac{1}{4}\left(\mathbf{F}_{j+i+1}+\mathbf{F}_{j-i+1}+\mathbf{F}_{j+i-1}+\mathbf{F}_{j-i-1}\right)
\end{aligned}
$$

## Obtaining the ROM from the data

- Suppose $\mathbf{U}$ is orthogonalized by a block $\mathbf{Q R}$ procedure

$$
\mathbf{U}=\mathbf{V L}^{T}
$$

so $\mathbf{V}=\mathbf{U L}{ }^{-T}$, where $\mathbf{L}$ is a block Cholesky factor of the Gramian $\mathbf{U}^{T} \mathbf{U}$ known from the data

$$
\mathbf{U}^{T} \mathbf{U}=\mathbf{L L}^{T}
$$

- The projection is given by

$$
\widetilde{\mathbf{P}}=\mathbf{V}^{T} \widehat{\mathbf{P}} \mathbf{V}=\mathbf{L}^{-1}\left(\mathbf{U}^{T} \widehat{\mathbf{P}} \mathbf{U}\right) \mathbf{L}^{-T}
$$

where $\mathbf{U}^{T} \widehat{\mathbf{P}} \mathbf{U}$ is also known from the data

- The use of Cholesky for orthogonalization is essential, (block) lower triangular structure is the linear algebraic equivalent of causality

## Use of ROMs

- Once we have the ROM $\widetilde{\mathbf{P}}=\mathbf{V}^{\top} \widehat{\mathbf{P}} \mathbf{V}, \widetilde{\mathbf{B}}=\mathbf{V}^{\top} \widehat{\mathbf{B}}$ how do we estimate c from it?
- The ROM for the operator $\mathbf{A}$ itself is

$$
\widetilde{\mathbf{A}}=\frac{2}{\tau^{2}}(\widetilde{\mathbf{P}}-\mathbf{I})
$$

from truncated Taylor's expansion

- Inversion: transform $\widetilde{\mathbf{A}}$ to a block finite difference (bFD) scheme, use the bFD coefficients in optimization
- Imaging: Using a smooth kinematic model $\mathbf{c}_{0}$ backproject $\widetilde{\mathbf{A}}$ to get the coefficient c directly

## Seismic inversion: optimization preconditioning

- Recall the conventional FWI (OLS)

$$
\underset{\mathbf{c}}{\operatorname{minimize}}\left\|\mathbf{F}^{\star}-\mathbf{F}(\cdot ; \mathbf{c})\right\|_{2}^{2}
$$

- Replace the objective with a "nonlinearly preconditioned" functional

$$
\underset{\mathbf{c}}{\operatorname{minimize}}\left\|\widetilde{\mathbf{A}}^{\star}-\widetilde{\mathbf{A}}(\mathbf{c})\right\|_{F}^{2}
$$

where $\widetilde{\mathbf{A}}^{\star}$ is computed from the data $\mathbf{F}^{\star}$ and $\widetilde{\mathbf{A}}(\mathbf{c})$ is a (highly) nonlinear mapping

$$
\tilde{\mathbf{A}}: \mathbf{c} \rightarrow \mathbf{A}(\mathbf{c}) \rightarrow \mathbf{U} \rightarrow \mathbf{V} \rightarrow \widetilde{\mathbf{P}} \rightarrow \tilde{\mathbf{A}}
$$

- Why does this have a preconditioning effect?

## Advantages of ROM-preconditioned optimization

- The biggest issue of conventional OLS FWI is the abundance of local minima (cycle skipping)
- The dependency of $\mathbf{A}(\mathbf{c})=\mathbf{c}^{2} \boldsymbol{\Delta}$ on $\mathbf{c}^{2}$ is linear
- In a certain parametrization the dependency of $\widetilde{\mathbf{A}}$ on $\mathbf{c}^{2}$ should be close to linear
- The preconditioned objective functional is close to quadratic, thus close to convex
- Approximate convexity leads to faster, more robust convergence
- Implicit orthogonalization of solution snapshots $\mathbf{V}=\mathbf{U L}^{-T}$ removes the multiple reflections

## Conventional vs. preconditioned in 1D

Conventional
CG iteration 1, $\mathrm{E}_{\mathrm{r}}=0.137937$

Preconditioned
CG iteration 1, $E_{r}=0.080594$

Faster convergence.

## Conventional vs. preconditioned in 1D

Conventional
CG iteration 5, $E_{r}=0.108350$

Preconditioned
CG iteration 5, $E_{r}=0.010831$

Faster convergence.

## Conventional vs. preconditioned in 1D

Conventional
$C G$ iteration 10, $E_{r}=0.081899$

Preconditioned
CG iteration 10, $E_{r}=0.002826$

Faster convergence.

## Conventional vs. preconditioned in 1D

Conventional
CG iteration 15, $E_{r}=0.070725$

Preconditioned
CG iteration 15, $E_{r}=0.002226$

Faster convergence.

## Conventional vs. preconditioned in 1D

Conventional
CG iteration 1, $\mathrm{E}_{\mathrm{r}}=0.278869$

Preconditioned
CG iteration 1, $E_{r}=0.272127$

## Automatic removal of multiple reflections.

## Conventional vs. preconditioned in 1D

Conventional
CG iteration 5, $E_{r}=0.265722$

Preconditioned
CG iteration 5, $E_{r}=0.197026$

Automatic removal of multiple reflections.

## Conventional vs. preconditioned in 1D

Conventional
$C G$ iteration 10, $E_{r}=0.273922$

Preconditioned
CG iteration 10, $E_{r}=0.157774$

Automatic removal of multiple reflections.

## Conventional vs. preconditioned in 1D

Conventional
CG iteration 15, $E_{r}=0.268569$

Preconditioned
CG iteration 15, $E_{r}=0.138945$

Automatic removal of multiple reflections.

## Conventional vs. preconditioned in 1D

Conventional
CG iteration 1, $\mathrm{E}_{\mathrm{r}}=0.173770$

Preconditioned
CG iteration 1, $E_{r}=0.147049$

## Avoiding the cycle skipping.

## Conventional vs. preconditioned in 1D

Conventional
CG iteration 5, $\mathrm{E}_{\mathrm{r}}=0.174695$

Preconditioned
CG iteration 5, $E_{r}=0.105966$

## Avoiding the cycle skipping.

## Conventional vs. preconditioned in 1D

Conventional
$C G$ iteration 10, $E_{r}=0.174688$

Preconditioned
CG iteration 10, $E_{r}=0.095547$

## Avoiding the cycle skipping.

## Conventional vs. preconditioned in 1D

Conventional
CG iteration 15, $E_{r}=0.174689$

Preconditioned
CG iteration 15, $E_{r}=0.086519$

## Avoiding the cycle skipping.

## Imaging: backprojection

- The ROM for $\tilde{\mathbf{A}}$ approximately satisfies

$$
\widetilde{\mathbf{A}} \approx \mathbf{V}^{\top} \widehat{\mathbf{A}} \mathbf{V}
$$

- If the subspace spanned by $\mathbf{V}$ is sufficiently rich, then

$$
\mathbf{v} \mathbf{v}^{T} \approx \mathbf{I}
$$

so we can backproject the ROM to the fine grid space

$$
\widehat{\mathbf{A}} \approx \mathbf{V} \widetilde{\mathbf{A}} \mathbf{V}^{\top} \approx \mathbf{V} \mathbf{V}^{\top} \widehat{\mathbf{A}} \mathbf{V} \mathbf{V}^{\top}
$$

- Problem: we do not know V, since the snapshots $\mathbf{U}$ are unknown to us in the whole domain
- Known smooth kinematic model $\mathbf{c}_{0}$ is needed
- From $c_{0}$ we can explicitly compute everything: $\widehat{\mathbf{A}}_{0}, \widetilde{\mathbf{A}}, \mathbf{U}_{0}$ and, most important, $\mathbf{V}_{0}$
- Replace the unknown true $\mathbf{V}$ by known $\mathbf{V}_{0}$

$$
\widehat{\mathbf{A}} \approx \mathbf{V}_{0} \widetilde{\mathbf{A}} \mathbf{V}_{0}^{T}
$$

## Backprojection: extracting the PDE coefficient

- We do not need the whole operator $\mathbf{A}$ or $\widehat{\mathbf{A}}$, just the fine grid coefficient $\mathbf{c}^{2}$
- Recall that $\widehat{\mathbf{A}}=\mathbf{C} \boldsymbol{\Delta} \mathbf{C}$, thus

$$
\mathbf{c}^{2} \propto \operatorname{diag}(\widehat{\mathbf{A}})
$$

- Similarly for the difference we have

$$
\delta \mathbf{c}^{2}=\mathbf{c}^{2}-\mathbf{c}_{0}^{2} \propto \operatorname{diag}\left(\widehat{\mathbf{A}}-\widehat{\mathbf{A}}_{0}\right)
$$

- Approximate $\widehat{\mathbf{A}}$ and $\widehat{\mathbf{A}}_{0}$ by their backprojections to obtain an imaging relation

$$
\delta \mathbf{c}^{2} \propto \operatorname{diag}\left(\mathbf{V}_{0}\left(\widetilde{\mathbf{A}}-\widetilde{\mathbf{A}}_{0}\right) \mathbf{V}_{0}^{T}\right)
$$

- Choosing different proportionality factors leads to various imaging formulae, for example a multiplicative

$$
\mathbf{c}^{\star}=\mathbf{c}_{0} \sqrt{1+\alpha \delta \mathbf{c}^{2}}
$$

## Backprojection imaging: features

- Conventional imaging techniques (Kirchhoff, RTM) are linear in the data
- Our approach is non-linear because of implicit orthogonalization

$$
\widetilde{\mathbf{P}}=\mathbf{L}^{-1}\left(\mathbf{U}^{T} \widehat{\mathbf{P}} \mathbf{U}\right) \mathbf{L}^{-T}, \quad \mathbf{U}^{T} \mathbf{U}=\mathbf{L L}^{T}
$$

- Block Cholesky: causal orthogonalization, removes the "tail", only the wavefront survives
- Thus, multiple reflection artifacts are removed
- We image correctly not only the locations of reflectors, but also their strength: true amplitude imaging
- Computationally cheap: we need a forward solution (same as RTM) and an extra orthogonalization step

## Removal of multiple reflection artifacts

True sound speed c

- A simple layered model, $p=12$ sources/receivers (black $\times$ )
- Multiple reflections from waves bouncing between layers and surface
- Each multiple creates an RTM artifact below actual layers

RTM image

Backprojection image

## Solution snapshot orthogonalization

- A 1D analogue of the previous example
- Strong primaries/multiples in $\mathbf{U}$, almost none in V
- The operator $\widehat{\mathbf{A}}$ is probed with $\mathbf{V}$ that is mostly a single propagating wavefront

## High contrast imaging: hydraulic fractures

True c

Backprojection difference $\mathbf{c}^{\star}-\mathbf{c}_{0}$

- Important application: seismic monitoring of hydraulic fracturing
- Multiple thin fractures (down to 1 cm in width, here 10 cm )
- Very high contrasts: $c=4500 \mathrm{~m} / \mathrm{s}$ in the surrounding rock, $c=1500 \mathrm{~m} / \mathrm{s}$ in the fluid inside fractures

## High contrast imaging: hydraulic fractures

- Important application: seismic monitoring of hydraulic fracturing
- Multiple thin fractures (down to 1 cm in width, here 10 cm )
- Very high contrasts: $c=4500 \mathrm{~m} / \mathrm{s}$ in the surrounding rock, $c=1500 \mathrm{~m} / \mathrm{s}$ in the fluid inside fractures

## Numerical example: Marmousi model

- Classical Marmousi model, $13.5 \mathrm{~km} \times 2.7 \mathrm{~km}$
- Forward problem is discretized on a 15 m grid with $N=900 \times 180=162,000$ nodes
- Kinematic model $\mathbf{c}_{0}$ : smoothed out true c ( 465 m horizontally, 315 m vertically)
- Time domain data sample rate $\tau=33.5 \mathrm{~ms}$, source frequency about $15 \mathrm{~Hz}, n=35$ data samples measured
- Number of sources/receivers $p=90$ uniformly distributed with spacing 150 m
- Data is split into 17 overlapping windows of 10 sources/receivers each (1.5km max offset)
- Reflecting boundary conditions
- No data filtering, everything used as is (surface wave, reflections from the boundaries, multiples)

Backprojection imaging

## Conclusions and future work

- Novel approach to seismic imaging using reduced order models
- Time domain formulation is essential, makes use of causality (linear algebraic analogue - Cholesky decomposition)
- Nonlinear construction of ROM via implicit causal orthogonalization of solution snapshots
- Strong suppression of multiple reflection artifacts

## Future work:

- Non-symmetric setting (non-collocated sources/receivers)
- Full waveform inversion in higher dimensions
- Better theoretical understanding
